Figure 1. The three Glacier National Park study sites are represented by black outlines. The dark blue dots represent breeding ponds and the light blue dots represent the random points for model placement.

Figure 2. Site 1 in Glacier National Park. Colors represent different toads and numbers indicate the sequence of relocations.

Figure 3. Site 2 in Glacier National Park. Colors represent different toads and numbers indicate the sequence of relocations.

Figure 4. Site 3 in Glacier National Park. Colors represent different toads and numbers indicate the sequence of relocations.

Figure 5. The burn severity levels associated with toad relocation on each date. Toads 1 through 9 are female toads and 10 through 22 are male toads. Black stars indicate toad locations in high severity burn areas, red stars indicate low to moderate severity locations, and green indicate locations in an unburned area. The only green star is from a toad location across Lake McDonald where a transmitter was located without a toad.

Animal ID

Figure 6. Number of relocations in each general habitat type. Toads were relocated in ponds until mid-July and then commonly relocated in forest and riparian habitats throughout the summer.

## General habitat type for toad relocations
